Relative Transforms

Introduction.

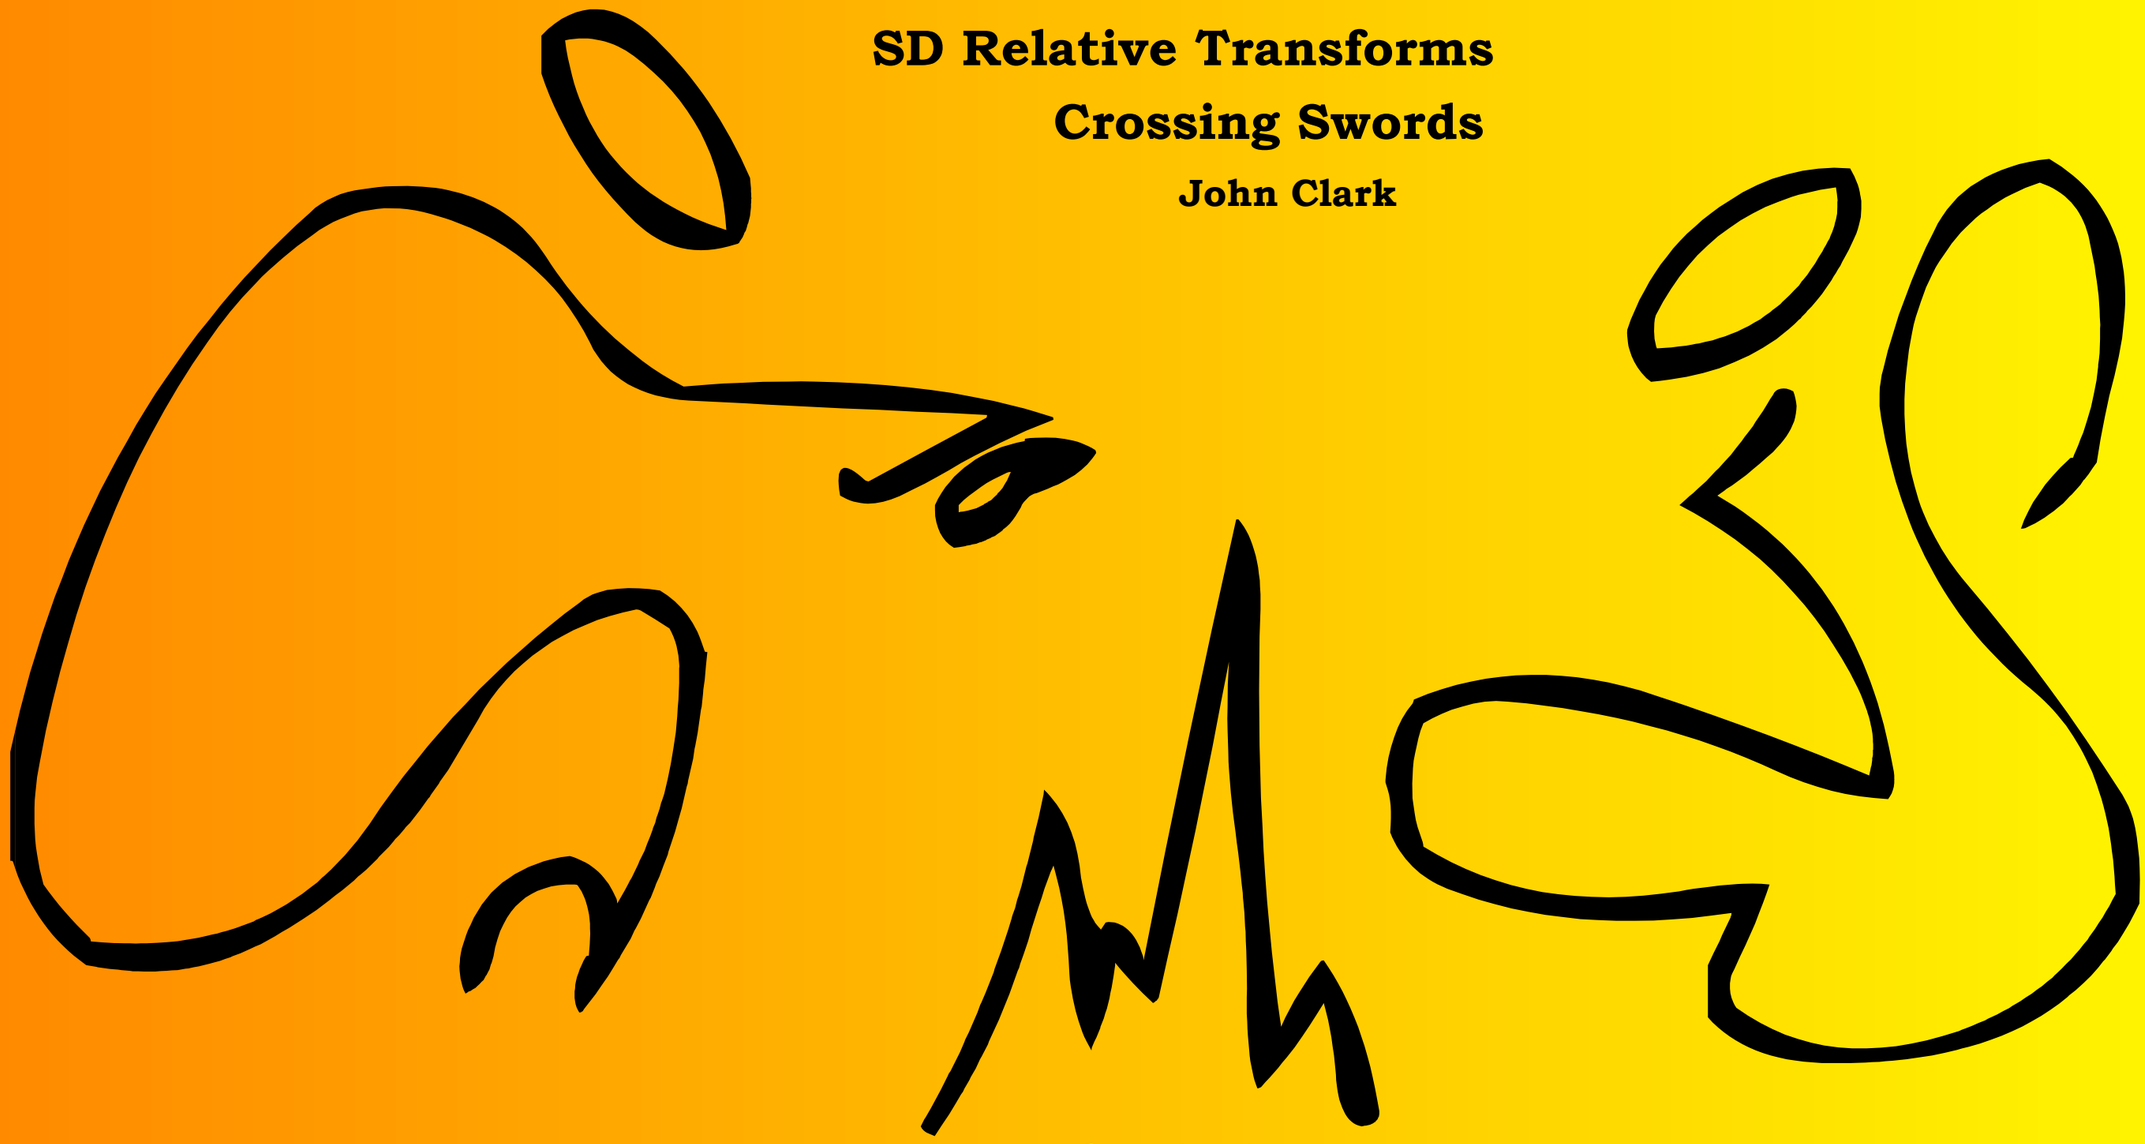
Each Glyph is composed of a number of variables. Ideally, a glyph when it is completed provides one variable for one relative difference. Although I use the term subset in this catalog, one can also use such phrases as family members. This means that each glyph actually represents a family of equations or one can call them a transform on a base glyph. A glyph of eight variables, or an equation of eight variables, provides us with a family of 256 derivative names in that family, or name for each family member. In short, that glyph can be drawn and worked, 256 ways, variants, or again expressions; this does not mean, however, that all of those equations are functional. Functionality depends upon the configuration.

Damn, now I am thinking maybe it is a book of genealogy.



This is a logging for examination of those family names for relative equations. As of this compilation, most equations are in the manner which Mathcad presented them. They have to be corrected to reflect a unit instead of a phrase. What I mean by this is that there are no such things as positive and negative numbers: a numeric phrase is not a number. Numeric phrases are for correlative processing, but the current method is generally wrong. If one wants to add constraints to an equation, then they would use logical operators. Any equation can be formulated as a logical operator. This means that any actual equation can have any other logical operator to form a compound expression or a specific result with a specific judgment as to a specific application.
